

Employing the Staticization Operator in Conservative Dynamical Systems and the Schrödinger Equation

William M. McEneaney^{*,†} Ruobing Zhao^{*,†}

Abstract—Conservative dynamical systems propagate as stationary points of the action functional. Hence, dynamical-systems questions may be addressed by control-theoretic methods. Using this representation, it has previously been demonstrated that one may obtain fundamental solutions for two-point boundary value problems for some classes of conservative systems via solution of an associated dynamic program. It is also known that the gravitational and Coulomb potentials may be represented as stationary points of cubically-parameterized quadratic functionals. Hence, stationary points of the action functional may be represented via iterated staticization of polynomial functionals. This leads to representations through operations on sets of solutions of differential Riccati equations (DREs). A key step in this process is the reordering of staticization operations.

Key words. dynamic programming, stationary action, staticization, two-point boundary value problems, Schrödinger equation, conservative dynamical systems.

I. INTRODUCTION

Conservative dynamical systems propagate as stationary points of the action functional over the possible paths of the system. This viewpoint appears particularly useful in certain domains of modern physics, including the areas of quantum and relativistic systems, cf. [4], [6], [20]. The stationary-action formulation has also recently been found to be quite useful for generation of fundamental solutions to two-point boundary-value problems (TPBVPs) for conservative dynamical systems, cf. [2], [16], [18]. In particular, one may address dynamical-systems questions such as these by control-theoretic methods. For example, one application to be discussed below will be TPBVPs in orbital mechanics.

To give a sense of this latter application domain, consider a finite-dimensional action-functional formulation of such a TPBVP. Let the path of the conservative system be denoted by ξ_r for $r \in [0, t]$ with $\xi_0 = \bar{x}$, in which case the action functional, with an appended terminal cost, may take the form

$$J(\bar{x}, t, u) \doteq \int_0^t T(u_r) - V(\xi_r) dr + \psi(\xi_t), \quad (1)$$

where $\dot{\xi} = u$, $u \in \mathcal{U} \doteq L_2(0, t)$, $T(\cdot)$ denotes the kinetic energy associated to the momentum (specifically taken to be $T(v) \doteq \frac{1}{2}v^T \mathcal{M}v$ throughout, with \mathcal{M} positive-definite and symmetric), and $V(\cdot)$ denotes a potential energy field. If, for example, one takes $\psi(x) \doteq -\bar{v}^T \mathcal{M}x$, a stationary-action path satisfies the TPBVP with $\xi_0 = \bar{x}$ and $\dot{\xi}_t = \bar{v}$; if one

takes ψ to be a min-plus delta function centered at z , then a stationary-action path satisfies the TPBVP with $\xi_0 = \bar{x}$ and $\xi_t = z$, cf. [2]. In the early work of Hamilton, it was formulated as the least-action principle [7], which states that a conservative dynamical system follows the trajectory that minimizes the action functional. However, this is typically only the case for relatively short-duration cases, cf. [6], [2], [18] and the references therein. In order to extend to longer-duration problems, it becomes necessary to apply concepts of stationarity [16], [17].

It is worth noting that if one defines $\text{stat}_{x \in \mathcal{X}} \phi(x)$ to be the critical value of ϕ (defined rigorously in Section II-A), then a gravitational potential given as $V(x) = -\mu/|x|$ for $x \neq 0$ and constant $\mu > 0$, has the representation $V(x) = -(\frac{3}{2})^{3/2} \mu \text{stat}_{\alpha > 0} \{\alpha - \frac{\alpha^3 |x|_c^2}{2}\}$, where we note that the argument of the staticization operator is polynomial, [8], [18]. The Schrödinger equation in the context of a Coulomb potential may be similarly addressed. In that case, it is particularly helpful to consider an extension of the space variable to a vector space over the complex field, say $x \in \mathbb{C}^n$ rather than $x \in \mathbb{R}^n$. More specifically, for $x \in \mathbb{C}^n$, this representation takes a general form $V(x) = -(\frac{3}{2})^{3/2} \hat{\mu} \text{stat}_{\alpha \in \mathcal{A}^R} \{\alpha - \frac{\alpha^3 |x|_c^2}{2}\}$, where $\mathcal{A}^R \doteq \{\alpha = r[\cos(\theta) + i \sin(\theta)] \in \mathbb{C} \mid r \geq 0, \theta \in (-\frac{\pi}{2}, \frac{\pi}{2}]\}$, and for $x \in \mathbb{C}^n$, $|x|_c^2 \doteq \sum_{j=1}^n x_j^2$, [12]. (We remark that notation $|\cdot|_c^2$ is not intended to indicate a squared norm; the range is complex.) In the simple one-dimensional case, the resulting function on \mathbb{C} has a branch cut along the negative imaginary axis, and this generalizes to the higher-dimensional case in the natural way.

Although stationarity-based representations for gravitational and Coulomb potentials are inside the integral in (1), they may be moved outside through the introduction of α -valued processes, cf. [8], [18]. In particular, not only does one seek the stationary path for action J , but the action functional itself can be given as a stationary value of an integral of a polynomial, leading to an iterated staticization problem formulation for such TPBVPs. This may be exploited in the solution of TPBVPs in such systems, cf. [8], [16], [18].

On a second front, it has recently been demonstrated that stationarity may be employed to obtain a Feynman-Kac type of representation for solutions of the Schrödinger initial value problem (IVP) for certain classes of initial conditions and potentials [15]. As with the conservative-system cases above, these representations are valid for indefinitely long duration problems, whereas with only the minimization operation, such representations are valid only on time intervals such

^{*}Research partially supported by a grant from AFOSR. [†]McEneaney, Zhao are with the Department of Mechanical and Aerospace Engineering, University of California at San Diego, La Jolla, CA 92093, USA. wmceneaney@ucsd.edu, ruz015@eng.ucsd.edu.

that the action remains convex.

In all of these examples, one obtains the stationary value of an action functional where the action functional itself takes the form of a stationary value of a functional that is quadratic in the momentum (the u . input in (1)) and cubic in the newly introduced potential energy parameterization variable (a time-dependent form of the α parameter above). That is, the overall stationary value is obtained from iterated staticization operations, where the outer staticization is over a variable in which the functional is quadratic. Thus, if one can invert the order of the staticization operations, then the inner staticization operation results in a functional that is obtained as a solution of a differential Riccati equation (DRE). (It should be noted that this DRE must typically be propagated past escape times, where this propagation may be efficiently performed through the use of what has been termed “stat duality”, cf. [13].) Hence, after inversion of the order of the iterated staticization operations, the problem may be reduced to a single staticization operation such that the argument takes the form of a linear functional operating on a set of DRE solutions. Consequently, an issue of fundamental importance regards conditions under which one may invert the order of staticization operations in an iterated staticization.

In Section II, the staticization operator will be rigorously defined, and a general problem class along with some corresponding notation will be indicated. Then, in Section III, a somewhat general condition will be indicated, and it will be shown that one may invert the order of staticization operations under that condition. Section IV will present several classes of problems for which the general condition of Section III holds. Finally, in Section V, the stationary-action applications will be discussed.

II. PROBLEM AND STATIONARITY DEFINITIONS

A. Stationarity definitions

As noted above, the motivation for this effort is the computation and propagation of stationary points of payoff functionals, which is unusual in comparison to the standard classes of problems in optimization (although one should note for example, [3]). In analogy with the language for minimization and maximization, we will refer to the search for stationary points as “staticization”, with these points being statica, in analogy with minima/maxima. We note that Ekeland [3] employed the term “extremization” for what is essentially the same notion that is being referred to here as staticization, but with different context and goals. We make the following definitions. Let \mathcal{F} denote either the real or complex field. Suppose \mathcal{U} is a normed vector space (over \mathcal{F}) with $\mathcal{A} \subseteq \mathcal{U}$, and suppose $G : \mathcal{A} \rightarrow \mathcal{F}$. We say $\bar{u} \in \text{argstat}_{u \in \mathcal{A}} G(u) \doteq \text{argstat}\{G(u) | u \in \mathcal{A}\}$ if $\bar{u} \in \mathcal{A}$ and either

$$\limsup_{u \rightarrow \bar{u}, u \in \mathcal{A} \setminus \{\bar{u}\}} \frac{|G(u) - G(\bar{u})|}{|u - \bar{u}|} = 0, \quad (2)$$

or \bar{u} is an isolated point of \mathcal{A} . If $\text{argstat}\{G(u) | u \in \mathcal{A}\} \neq \emptyset$, we define the possibly set-valued stat^s operation by

$$\begin{aligned} \text{stat}_{u \in \mathcal{A}}^s G(u) &\doteq \text{stat}^s\{G(u) | u \in \mathcal{A}\} \\ &\doteq \{G(\bar{u}) | \bar{u} \in \text{argstat}\{G(u) | u \in \mathcal{A}\}\}. \end{aligned} \quad (3)$$

If $\text{argstat}\{G(u) | u \in \mathcal{A}\} = \emptyset$, $\text{stat}_{u \in \mathcal{A}}^s G(u)$ is undefined. Where applicable, we are also interested in a single-valued staticization operation (note the absence of superscript s). In particular, if there exists $a \in \mathcal{F}$ such that $\text{stat}_{u \in \mathcal{A}}^s G(u) = \{a\}$, then $\text{stat}_{u \in \mathcal{A}} G(u) \doteq a$; otherwise, $\text{stat}_{u \in \mathcal{A}} G(u)$ is undefined. At times, we may abuse notation by writing $\bar{u} = \text{argstat}\{G(u) | u \in \mathcal{A}\}$ in the event that the argstat is the single point $\{\bar{u}\}$. The following is immediate from the above definitions.

Lemma 1: Suppose \mathcal{U} is a Banach space, with open set $\mathcal{A} \subseteq \mathcal{U}$, and that G is Fréchet differentiable at $\bar{u} \in \mathcal{A}$. Then, $\bar{u} \in \text{argstat}\{G(y) | y \in \mathcal{A}\}$ if and only if the Fréchet derivative is zero at \bar{u} .

B. Problem definition

Let \mathcal{U}, \mathcal{V} be Banach spaces with norms on \mathcal{U} denoted by $|\cdot|_{\mathcal{U}}$, and similarly for \mathcal{V} . When \mathcal{U} is also Hilbert, let the inner product be denoted by $\langle \cdot, \cdot \rangle_{\mathcal{U}}$. Let $\mathcal{A} \subseteq \mathcal{U}$ and $\mathcal{B} \subseteq \mathcal{V}$ be open. Throughout, we assume

$$G \in C^2(\mathcal{A} \times \mathcal{B}; \mathcal{F}). \quad (A.1)$$

Then, for each $u \in \mathcal{A}$, let $g^{1,u} \in C^2(\mathcal{B}; \mathcal{F})$ be given by $g^{1,u}(v) \doteq G(u, v)$ for all $v \in \mathcal{B}$. Similarly, for each $v \in \mathcal{B}$, let $g^{2,v} \in C^2(\mathcal{A}; \mathcal{F})$ be given by $g^{2,v}(u) \doteq G(u, v)$ for all $u \in \mathcal{A}$. Further, let

$$\begin{aligned} \mathcal{A}_G &\doteq \{u \in \mathcal{A} | \text{stat}_{v \in \mathcal{B}} g^{1,u}(v) \text{ exists}\} \quad \text{and} \\ \mathcal{B}_G &\doteq \{v \in \mathcal{B} | \text{stat}_{u \in \mathcal{A}} g^{2,v}(u) \text{ exists}\}. \end{aligned} \quad (4)$$

Given $u \in \mathcal{A}_G$, let $\mathcal{M}^1(u) \doteq \text{argstat}_{v \in \mathcal{B}} g^{1,u}(v)$. Similarly, given $v \in \mathcal{B}_G$, let $\mathcal{M}^2(v) \doteq \text{argstat}_{u \in \mathcal{A}} g^{2,v}(u)$. Next, define $\bar{G}^1 : \mathcal{A}_G \rightarrow \mathcal{F}$ and $\bar{G}^2 : \mathcal{B}_G \rightarrow \mathcal{F}$ by

$$\begin{aligned} \bar{G}^1(u) &\doteq \text{stat}_{v \in \mathcal{B}} g^{1,u}(v) \quad \forall u \in \mathcal{A}_G \quad \text{and} \\ \bar{G}^2(v) &\doteq \text{stat}_{u \in \mathcal{A}} g^{2,v}(u) \quad \forall v \in \mathcal{B}_G. \end{aligned}$$

Finally, let

$$\hat{\mathcal{A}}_G \doteq \text{argstat}_{u \in \mathcal{A}_G} \bar{G}^1(u) \quad \text{and} \quad \hat{\mathcal{B}}_G \doteq \text{argstat}_{v \in \mathcal{B}_G} \bar{G}^2(v).$$

We will discuss conditions under which

$$\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u) = \text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v) = \text{stat}_{v \in \mathcal{B}_G} \bar{G}^2(v). \quad (5)$$

We will generally be concerned only with the left-hand equality in (5); obviously the right-hand equality would be obtained analogously. We refer to the left-hand object in (5) as iterated stat operations, while the center object will be referred to as a full stat operation. Although in some results, the existence of both the iterated and full stat operations are obtained, many of the results will assume the existence of one or both of these objects. We list the two potential assumptions

below. In each result to follow, we will indicate when one or both of these is utilized. The full-stat assumption is as follows.

Assume $\text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$ exists, and let $(\bar{u}, \bar{v}) \in \arg\text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$. (A.2f)

Note that under Assumption (A.2f),

$$\bar{u} \in \mathcal{A}_G, \bar{v} \in \mathcal{B}_G, \bar{v} \in \mathcal{M}^1(\bar{u}), \text{ and } \bar{u} \in \mathcal{M}^2(\bar{v}). \quad (6)$$

The iterated-stat assumption is as follows.

Assume $\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u)$ exists, and let $\bar{u} \in \hat{\mathcal{A}}_G$. (A.2i)

Note that under Assumption (A.2i),

$$\exists \bar{v} \in \mathcal{M}^1(\bar{u}), \text{ and } \text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u) = g^{1, \bar{u}}(\bar{v}) = G(\bar{u}, \bar{v}). \quad (7)$$

We will first obtain (5) under some general assumptions.

III. THE GENERAL CASE

Given $\mathcal{C} \subseteq \mathcal{V}$ and $\hat{v} \in \mathcal{V}$, we let $d(\hat{v}, \mathcal{C}) \doteq \inf_{v \in \mathcal{C}} |v - \hat{v}|$, and use this distance notation more generally throughout. In addition to (A.1), we assume the following throughout this section.

There exist $\delta = \delta(\bar{u}, \bar{v}) > 0$ and $K = K(\bar{u}, \bar{v}) < \infty$ such that $d(\bar{v}, \mathcal{M}^1(u)) \leq K |\bar{u} - u|$ for all $u \in \mathcal{A}_G \cap B_\delta(\bar{u})$. (A.3)

We note that (A.3) is trivially satisfied in the case that there exists $\delta > 0$ such that $B_\delta(\bar{u}) \cap \mathcal{A}_G = \emptyset$. It may be helpful to also note that (A.3) is satisfied under the possibly more heuristically appealing, following assumption.

For every $\tilde{u} \in \mathcal{A}_G$ and every $\tilde{v} \in \mathcal{M}^1(\tilde{u})$, there exist $\delta = \delta(\tilde{u}, \tilde{v}) > 0$ and $K = K(\tilde{u}, \tilde{v}) < \infty$ such that $d(\tilde{v}, \mathcal{M}^1(u)) \leq K |\tilde{u} - u|$ for all $u \in \mathcal{A}_G \cap B_\delta(\tilde{u})$. (A.3')

Lemma 2: Assume (A.2f). Then, $\bar{u} \in \hat{\mathcal{A}}_G$ and $G(\bar{u}, \bar{v}) \in \text{stat}_{u \in \mathcal{A}_G}^s \bar{G}^1(u)$.

Proof: Let (\bar{u}, \bar{v}) be as in (A.2f). Let $R \doteq d((\bar{u}, \bar{v}), (\mathcal{A} \times \mathcal{B})^c)$. By Assumption (A.3), there exist $\delta \in (0, R/2)$ and $K < \infty$ such that for all $u \in \mathcal{A}_G \cap B_\delta(\bar{u})$ and all $\epsilon \in (0, 1)$, there exists $v \in \mathcal{M}^1(u)$ such that

$$|v - \bar{v}| \leq (K + \epsilon)|u - \bar{u}| \leq (K + \epsilon)\delta. \quad (8)$$

Let $\tilde{u} \in \mathcal{A}_G \cap B_{\delta/(K+1)}(\bar{u})$. By (6),

$$|\text{stat}_{v \in \mathcal{B}} g^{1, \tilde{u}}(v) - \text{stat}_{v \in \mathcal{B}} g^{1, \bar{u}}(v)| = |\text{stat}_{v \in \mathcal{B}} g^{1, \tilde{u}}(v) - G(\bar{u}, \bar{v})|,$$

and by (8), there exists $\tilde{v} \in B_\delta(\bar{v})$ such that this is

$$= |G(\tilde{u}, \tilde{v}) - G(\bar{u}, \bar{v})|. \quad (9)$$

Let $f \in C^\infty((-3/2, 3/2); \mathcal{A} \times \mathcal{B})$ be given by $f(\lambda) = (\bar{u} + \lambda(\tilde{u} - \bar{u}), \bar{v} + \lambda(\tilde{v} - \bar{v}))$ for all $\lambda \in (-3/2, 3/2)$. Define $W^0(\lambda) = [G \circ f](\lambda)$ for all $\lambda \in (-3/2, 3/2)$, and note that by Assumption (A.1) and standard results, $W^0 \in C^2((-3/2, 3/2); \mathcal{F})$. Similarly, let $W^1(\lambda) = [(G_u, G_v) \circ f](\lambda) = (G_u(f(\lambda)), G_v(f(\lambda)))$. By Assumption (A.1) and standard results, $W^1 \in C^1((-3/2, 3/2); \mathcal{U} \times \mathcal{V})$. Then, by

the Mean Value Theorem (cf. [1, Th. 12.6]), there exists $\lambda_0 \in (0, 1)$ such that

$$\begin{aligned} |G(\tilde{u}, \tilde{v}) - G(\bar{u}, \bar{v})| &= |W^0(1) - W^0(0)| \\ &\leq \left| \frac{dG}{d(u, v)}(f(\lambda_0)) \right| \left| \frac{df}{d\lambda}(\lambda_0) \right| \\ &= |(G_u(u_0, v_0), G_v(u_0, v_0))| |(\tilde{u} - \bar{u}, \tilde{v} - \bar{v})|, \end{aligned}$$

where $(u_0, v_0) \doteq f(\lambda_0)$, and which by (8),

$$\leq |(G_u(u_0, v_0), G_v(u_0, v_0))| \sqrt{1 + (K + 1)^2} |\tilde{u} - \bar{u}|. \quad (10)$$

Similarly, there exists $\lambda_1 \in (0, \lambda_0)$ such that

$$\begin{aligned} |(G_u(u_0, v_0), G_v(u_0, v_0)) - (G_u(\bar{u}, \bar{v}), G_v(\bar{u}, \bar{v}))| \\ = |W^1(\lambda_0) - W^1(0)| \leq \left| \frac{d^2 G}{d(u, v)^2}(f(\lambda_1)) \right| \left| \frac{df}{d\lambda}(\lambda_1) \right| |\lambda_1| \\ \leq \left| \frac{d^2 G}{d(u, v)^2}(u_1, v_1) \right| |(u_1 - \bar{u}, v_1 - \bar{v})|, \end{aligned}$$

where $(u_1, v_1) \doteq f(\lambda_1)$, and this is

$$\leq \left| \frac{d^2 G}{d(u, v)^2}(f(\lambda_1)) \right| \sqrt{1 + (K + 1)^2} |\tilde{u} - \bar{u}|.$$

Recalling $(\bar{u}, \bar{v}) \in \arg\text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$, this implies

$$\begin{aligned} |(G_u(u_0, v_0), G_v(u_0, v_0))| \\ \leq \left| \frac{d^2 G}{d(u, v)^2}(f(\lambda_1)) \right| \sqrt{1 + (K + 1)^2} |\tilde{u} - \bar{u}|. \quad (11) \end{aligned}$$

Combining (10) and (11) yields

$$|G(\tilde{u}, \tilde{v}) - G(\bar{u}, \bar{v})| \leq \left| \frac{d^2 G}{d(u, v)^2}(f(\lambda_1)) \right| [1 + (K + 1)^2] |\tilde{u} - \bar{u}|^2.$$

Let $K_1 \doteq \left| \frac{d^2 G}{d(u, v)^2}(\bar{u}, \bar{v}) \right|$. By (A.1), there exists $\hat{\delta} \in (0, \delta/(K + 1))$ such that for all $(u, v) \in B_{\hat{\delta}}(\bar{u}, \bar{v})$, $\left| \frac{d^2 G}{d(u, v)^2}(u, v) \right| \leq K_1 + 1$. Hence, there exists $\bar{C} < \infty$ such that

$$|G(\tilde{u}, \tilde{v}) - G(\bar{u}, \bar{v})| \leq \bar{C} |\tilde{u} - \bar{u}|^2 \quad \forall (\tilde{u}, \tilde{v}) \in \mathcal{A}_G \cap B_{\hat{\delta}/(K_1+1)}(\bar{u}). \quad (12)$$

Combining (9) and (12) one has $|\text{stat}_{v \in \mathcal{B}} g^{1, \tilde{u}}(v) - \text{stat}_{v \in \mathcal{B}} g^{1, \bar{u}}(v)| \leq \bar{C} |\tilde{u} - \bar{u}|^2$, which upon recalling that $\tilde{u} \in \mathcal{A}_G \cap B_{\hat{\delta}/(K+1)}(\bar{u})$ was arbitrary, yields the assertions. \blacksquare

Theorem 3: Assume (A.2f) and (A.2i). Then

$$\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u) = G(\bar{u}, \bar{v}) = \text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v).$$

IV. SOME SPECIFIC CASES

A. The Semi-Quadratic Case

We take $\mathcal{A} \subseteq \mathcal{U}$ and $\mathcal{B} = \mathcal{V}$, with \mathcal{V} being Hilbert. Let

$$G(u, v) \doteq f_1(u) + \langle f_2(u), v \rangle_{\mathcal{V}} + \frac{1}{2} \langle \bar{B}_3(u) v, v \rangle_{\mathcal{V}}, \quad (13)$$

for all $u \in \mathcal{A}$ and $v \in \mathcal{V}$, where $f_1 \in C^2(\mathcal{A}; \mathcal{F})$, $f_2 \in C^2(\mathcal{A}; \mathcal{V})$ and $\bar{B}_3 \in C^2(\mathcal{A}; \mathcal{L}(\mathcal{V}, \mathcal{V}))$, and $\bar{B}_3(u)$ is self-adjoint and closed for all $u \in \mathcal{A}$. For each $u \in \mathcal{A}$, let $\bar{B}_3^\#(u) \doteq [\bar{B}_3(u)]^\#$ denote the Moore-Penrose pseudo-inverse of $\bar{B}_3(u)$. Assume that there exists a constant $D > 0$ such that $|\bar{B}_3^\#(u)| \leq D$ for all $u \in \mathcal{A}_G$.

Lemma 4: Let $\hat{u} \in \mathcal{A}$. Then $\hat{v} \in \mathcal{M}^1(\hat{u})$ if and only if $f_2(\hat{u}) + \bar{B}_3(\hat{u})\hat{v} = 0$.

1) When the full staticization is known to exist:

Lemma 5: Assume (A.2f). Then assumption (A.3) is satisfied.

Proof: The result is trivial for $\mathcal{A} = \{\bar{u}\}$. Suppose $\mathcal{A}_G \neq \{\bar{u}\}$. Choose an $\delta > 0$ such that $\mathcal{A}_G \cap (B_\delta(\bar{u}) \setminus \{\bar{u}\}) \neq \emptyset$. Let $\hat{u} \in \mathcal{A}_G \cap B_\delta(\bar{u})$, and $\hat{u} \neq \bar{u}$. Let $\hat{v} = \bar{v} - \bar{B}_3^\#(\hat{u})f_2(\hat{u}) - \bar{B}_3^\#(\hat{u})\bar{B}_3(\hat{u})\bar{v}$. By properties of pseudoinverse, we have $\bar{B}_3(\hat{u})\hat{v} + f_2(\hat{u}) = \bar{B}_3(\hat{u})[\bar{v} - \bar{B}_3^\#(\hat{u})f_2(\hat{u}) - \bar{B}_3^\#(\hat{u})\bar{B}_3(\hat{u})\bar{v}] + f_2(\hat{u}) = \bar{B}_3(\hat{u})\bar{v} - f_2(\hat{u}) - \bar{B}_3(\hat{u})\bar{v} + f_2(\hat{u}) = 0$. Therefore, $\hat{v} \in \mathcal{M}^1(\hat{u})$ by Lemma 4. Letting $K_f = \max_{\lambda \in [0,1]} \left| \frac{df_2}{d\hat{u}}(\lambda\hat{u} + (1-\lambda)\bar{u}) \right|$ and $K_B = \max_{\lambda \in [0,1]} \left| \frac{d\bar{B}_3}{d\hat{u}}(\lambda\hat{u} + (1-\lambda)\bar{u}) \right|$, we have

$$\begin{aligned} |\hat{v} - \bar{v}| &= \left| -\{\bar{B}_3^\#(\hat{u})f_2(\hat{u}) + \bar{B}_3^\#(\hat{u})\bar{B}_3(\hat{u})\bar{v}\} \right| \\ \text{By Lemma 4, } \bar{B}_3(\bar{u})\bar{v} + f_2(\bar{u}) &= 0, \\ &= \left| -\bar{B}_3^\#(\hat{u})\{f_2(\hat{u}) - f_2(\bar{u}) - \bar{B}_3(\bar{u})\bar{v} + \bar{B}_3(\hat{u})\bar{v}\} \right| \\ &\leq |\bar{B}_3^\#(\hat{u})| |f_2(\hat{u}) - f_2(\bar{u}) + (\bar{B}_3(\hat{u}) - \bar{B}_3(\bar{u}))\bar{v}| \\ &\leq D \left[K_f |\hat{u} - \bar{u}| + K_B |\bar{v}| |\hat{u} - \bar{u}| \right] \end{aligned}$$

which gives (A.3). \blacksquare

Theorem 6: Assume (A.2f). Then $\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u)$ exists, and $\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u) = G(\bar{u}, \bar{v}) = \text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$.

2) When the iterated staticization is known to exist: The case where the iterated staticization is known to exist appears to require a substantial additional assumption.

Theorem 7: Assume (A.2i). Assume that $f_2(u) \in \text{Range}[\bar{B}_3(u)]$ for all $u \in \mathcal{A}_G$. Then $\text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$ exists, and $\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u) = G(\bar{u}, \bar{v}) = \text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$.

Proof: Note that by assumption and Lemma 4, $\mathcal{A}_G = \mathcal{A}$. Let $\bar{u} \in \hat{\mathcal{A}}_G$, and let \bar{v} be as in (7), which implies

$$G_v(\bar{u}, \bar{v}) = 0. \quad (14)$$

Suppose $G_u(\bar{u}, \bar{v}) \neq 0$. Then there exists $\epsilon > 0$ and $u_n \in \mathcal{A} \setminus \{\bar{u}\}$ with $u_n \rightarrow \bar{u}$ such that given $\epsilon > 0$, there exists $\bar{n} = \bar{n}(\epsilon) \in \mathbb{N}$ such that

$$|G(u_n, \bar{v}) - G(\bar{u}, \bar{v})| > \epsilon |u_n - \bar{u}| \quad \forall n \geq \bar{n}. \quad (15)$$

Let $v_n \doteq \bar{v} - \bar{B}_3^\#(u_n)[f_2(u_n) + \bar{B}_3(u_n)\bar{v}] \quad \forall n \in \mathbb{N}$. Note that using Lemma 4,

$$\begin{aligned} |v_n - \bar{v}| &\leq |\bar{B}_3^\#(u_n)| |f_2(u_n) + \bar{B}_3(u_n)\bar{v} - f_2(\bar{u}) - \bar{B}_3(\bar{u})\bar{v}|, \end{aligned}$$

which by assumption,

$$\leq D(|f_2(u_n) - f_2(\bar{u})| + |\bar{B}_3(u_n) - \bar{B}_3(\bar{u})||\bar{v}|),$$

and by the Mean Value Theorem and the smoothness of f_2, \bar{B}_3 , there exists $K < \infty$, and $\hat{n} \in \mathbb{N}$ such that this is

$$\leq DK(1 + |\bar{v}|)|u_n - \bar{u}| \quad \forall n \geq \hat{n}. \quad (16)$$

Also, by assumption and the properties of the pseudo-inverse, $\bar{B}_3(u_n)v_n + f_2(u_n) = \bar{B}_3(u_n)[\bar{v} - \bar{B}_3^\#(u_n)f_2(u_n) -$

$\bar{B}_3^\#(u_n)\bar{B}_3(u_n)\bar{v}] + f_2(u_n) = \bar{B}_3(u_n)\bar{v} - f_2(u_n) - \bar{B}_3(u_n)\bar{v} + f_2(u_n) = 0$, and hence, $v_n \in \mathcal{M}_1(u_n)$ for all $n \in \mathbb{N}$.

By (A.2i), there exists $\bar{n} = \bar{n}(\epsilon)$ such that for all $n \geq \bar{n}$,

$$|G(u_n, v_n) - G(\bar{u}, \bar{v})| = |\bar{G}^1(u_n) - \bar{G}^1(\bar{u})| < \frac{\epsilon}{2} |u_n - \bar{u}|,$$

which implies

$$|G(u_n, v_n) - G(u_n, \bar{v}) + G(u_n, \bar{v}) - G(\bar{u}, \bar{v})| < \frac{\epsilon}{2} |u_n - \bar{u}|,$$

and hence $\forall n \geq \bar{n}$

$$|G(u_n, \bar{v}) - G(\bar{u}, \bar{v})| < \frac{\epsilon}{2} |u_n - \bar{u}| + |G(u_n, v_n) - G(u_n, \bar{v})| \quad (17)$$

Now, by (13), for any $v \in \mathcal{B}$,

$$\begin{aligned} G(u_n, v) - G(u_n, v_n) &= \langle f_2(u_n) + \frac{1}{2}\bar{B}_3(u_n)v, v \rangle - \langle f_2(u_n) + \frac{1}{2}\bar{B}_3(u_n)v_n, v_n \rangle, \\ \text{which by Lemma 4, the choice of } v_n \text{ and the self-adjointness of } \bar{B}_3(u_n), \\ &= \langle -\bar{B}_3(u_n)v_n + \frac{1}{2}\bar{B}_3(u_n)v, v \rangle + \frac{1}{2}\langle \bar{B}_3(u_n)v_n, v_n \rangle \\ &= \frac{1}{2}\langle \bar{B}_3(u_n)(v - v_n), v - v_n \rangle. \end{aligned} \quad (18)$$

Applying (16) in (18), we see that there exists $K_1 < \infty$ such that $|G(u_n, \bar{v}) - G(u_n, v_n)| \leq K_1 |u_n - \bar{u}|^2$ for all $n \in \mathbb{N}$, and consequently, there exists $\bar{n}_1 = \bar{n}_1(\epsilon) < \infty$ such that

$$|G(u_n, \bar{v}) - G(u_n, v_n)| < \frac{\epsilon}{2} |u_n - \bar{u}| \quad \forall n \geq \bar{n}_1. \quad (19)$$

By (17) and (19),

$$|G(u_n, \bar{v}) - G(\bar{u}, \bar{v})| < \epsilon |u_n - \bar{u}| \quad \forall n \geq \bar{n} \wedge \bar{n}_1. \quad (20)$$

However, (20) contradicts (15), and consequently,

$$G_u(\bar{u}, \bar{v}) = 0. \quad (21)$$

By (14) and (21), $(\bar{u}, \bar{v}) \in \text{argstat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$ and $G(\bar{u}, \bar{v}) \in \text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$.

Now suppose $\exists(\hat{u}, \hat{v}) \in \text{argstat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v) \setminus \{(\bar{u}, \bar{v})\}$. This implies

$$\begin{aligned} G_u(\hat{u}, \hat{v}) &= 0, \quad G_v(\hat{u}, \hat{v}) = 0, \\ \hat{v} &\in \mathcal{M}^1(\hat{u}), \quad \text{and } \bar{G}^1(\hat{u}) = G(\hat{u}, \hat{v}). \end{aligned} \quad (22)$$

Let $\check{v}(u) \doteq \hat{v} - \bar{B}_3^\#(u)f_2(u) - \bar{B}_3^\#(u)\bar{B}_3(u)\hat{v} \quad \forall u \in \mathcal{A}$, and note that $\check{v}(\hat{u}) = \hat{v}$. Again, we see that $\bar{B}_3(u)\check{v}(u) + f_2(u) = 0$, which implies that $\check{v}(u) \in \mathcal{M}^1(u)$ for all $u \in \mathcal{A}$. Hence, $\bar{G}^1(u) = G(u, \check{v}(u))$ for all $u \in \mathcal{A}$. Note that

$$\begin{aligned} |\bar{G}^1(u) - \bar{G}^1(\hat{u})| &= |G(u, \check{v}(u)) - G(\hat{u}, \hat{v})| \\ &\leq |G(u, \check{v}(u)) - G(u, \hat{v})| + |G(u, \hat{v}) - G(\hat{u}, \hat{v})|, \end{aligned}$$

and note that by (22), given $\epsilon > 0$, there exists $\hat{\delta}_1 = \hat{\delta}_1(\epsilon) > 0$ such that for all $|u - \hat{u}| < \hat{\delta}_1$,

$$\leq \frac{\epsilon}{2} |u - \hat{u}| + |G(u, \check{v}(u)) - G(u, \hat{v})|. \quad (23)$$

Also, similar to the estimate (19), we also find that there exists $\hat{\delta}_2 = \hat{\delta}_2(\epsilon) > 0$ such that

$$|G(u, \check{v}(u)) - G(u, \hat{v})| < \frac{\epsilon}{2} |u - \hat{u}| \quad \forall |u - \hat{u}| < \hat{\delta}_2.$$

Using this in (23), we see that

$$|\bar{G}^1(u) - \bar{G}^1(\hat{u})| < \epsilon |u - \hat{u}| \quad \forall |u - \hat{u}| < \hat{\delta}_1 \wedge \hat{\delta}_2. \quad (24)$$

Hence, $\frac{d\bar{G}^1}{du}(\hat{u}) = 0$, which implies that $\hat{u} \in \hat{\mathcal{A}}_G$. Using this and (A.2i), we see that $G(\hat{u}, \hat{v}) = G(\bar{u}, \bar{v})$. As $(\hat{u}, \hat{v}) \in \text{argstat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v) \setminus \{(\bar{u}, \bar{v})\}$ was arbitrary, we have the desired result. ■

B. The Uniformly Morse Case

We assume that for all $(\hat{u}, \hat{v}) \in \mathcal{A} \times \mathcal{B}$ such that $G_v(\hat{u}, \hat{v}) = 0$, there exist $\tilde{\epsilon} = \tilde{\epsilon}(\hat{u}, \hat{v}) > 0$ and $\tilde{K} = \tilde{K}(\hat{u}, \hat{v}) < \infty$ such that $G_{vv}(u, v)$ is invertible with $||G_{vv}(u, v)||^{-1} \leq \tilde{K}$ for all $(u, v) \in B_{\tilde{\epsilon}}(\hat{u}, \hat{v})$. We also assume that $G_{uv}(u, v)$ is bounded on bounded sets. Under these assumptions and (A.1), we will find that Assumption (A.3') holds. Hence, one may apply Theorem 3.

Lemma 8: Assume (A.2f). There exist $\epsilon, \delta > 0$ and $\check{v} \in C^1(B_\epsilon(\bar{u}); \mathcal{B} \cap B_\delta(\bar{v}))$ such that $B_\epsilon(\bar{u}) \subseteq \mathcal{A}_G$, $\check{v}(\bar{u}) = \bar{v}$, $G_v(u, \check{v}(u)) = 0$ and $\frac{d\check{v}}{du}(u) = -[G_{vv}(u, v)|_{(u, \check{v}(u))}]^{-1} G_{uv}(u, v)|_{(u, \check{v}(u))}$ for all $u \in B_\epsilon(\bar{u})$.

Lemma 9: Assume (A.2f). Then, there exists $K < \infty$ and $\delta \in (0, \epsilon)$ such that $|\check{v}(u) - \check{v}(\bar{u})| = |\check{v}(u) - \bar{v}| \leq K|u - \bar{u}|$ for all $u \in B_\delta(\bar{u}) \subseteq \mathcal{A}_G$.

Lemma 10: Assume (A.2f). Then, $\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u)$ exists.

Theorem 11: Assume (A.2f). Then, $\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u)$ exists, and $\text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u) = G(\bar{u}, \bar{v}) = \text{stat}_{(u,v) \in \mathcal{U} \times \mathcal{V}} G(u, v)$.

1) When the iterated staticization is known to exist:

Lemma 12: Assume (A.2i). Then, $\text{stat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$ exists.

Theorem 13: Assume (A.2i). Then, $\text{argstat}_{(u,v) \in \mathcal{A} \times \mathcal{B}} G(u, v)$ exists, and $\text{stat}_{(u,v) \in \mathcal{U} \times \mathcal{V}} G(u, v) = G(\bar{u}, \bar{v}) = \text{stat}_{u \in \mathcal{A}_G} \bar{G}^1(u)$.

V. APPLICATIONS TO ASTRODYNAMICS AND THE SCHRÖDINGER EQUATION

A. TPBVPs in Astrodynamics

One may obtain fundamental solutions to TPBVPs in astrodynamics through a stationary-action based approach [8], [9], [16], [18]. We briefly recall the case of the n -body problem. In this case, the action functional with an appended terminal cost (cf. [18]) takes the form indicated in (1), where now $x = ((x^1)^T, (x^2)^T, \dots, (x^n)^T)^T$, where each $x^j \in \mathbb{R}^3$ denotes a generic position of body $j \in \mathcal{N} \doteq \{1, 2, \dots, n\}$, and ξ, u are similarly constructed. The kinetic-energy term is $T(u_r) \doteq \frac{1}{2} \sum_{j=1}^n m_j |u_r^j|^2$, where m_j is the mass of the j^{th} body. The additive inverse of the potential at any $x \in \mathbb{R}^{3n}$ is given by

$$\begin{aligned} -V(x) &= \sum_{(i,j) \in \mathcal{I}^\Delta} \frac{\Gamma m_i m_j}{|x^i - x^j|} \\ &= \max_{\alpha \in \mathcal{M}_{(0,\infty)}} \sum_{(i,j) \in \mathcal{I}^\Delta} \left(\frac{3}{2}\right)^{3/2} \Gamma m_i m_j \left[\alpha_{i,j} - \frac{\alpha_{i,j}^3 |x^i - x^j|^2}{2} \right] \\ &\doteq \max_{\alpha \in \mathcal{M}_{(0,\infty)}} [-\tilde{V}(x, \alpha)] = -\tilde{V}(x, \tilde{\alpha}), \end{aligned}$$

where Γ is the universal gravitational constant, $\mathcal{I}^\Delta \doteq \{(i, j) \in \mathcal{N}^2 \mid j > i\}$, $\mathcal{M}_{(0,\infty)}$ denotes the set of arrays indexed by $(i, j) \in \mathcal{I}^\Delta$ with elements in $(0, \infty)$, and $\tilde{\alpha}_{i,j} = \tilde{\alpha}_{i,j}(x) = [2/(3|x^i - x^j|^2)]^{1/2}$ for all $(i, j) \in \mathcal{I}^\Delta$; see [18]. Letting $\mathcal{U}_{(0,t)} \doteq L_2((0, t); \mathbb{R}^{3n})$, one finds that the problem becomes that of finding the stationary-action value function given by

$$W(t, x) = \text{stat}_{u \in \mathcal{B}} J^0(t, x, u), \quad (25)$$

where $J^0(t, x, u) \doteq \int_0^t T(u_r) - V(\xi_r) dr + \phi(\xi_t) = \int_0^t T(u_r) + \max_{\alpha \in \mathcal{M}_{(0,\infty)}} [-\tilde{V}(x, \alpha)] dr + \phi(\xi_t)$, $\mathcal{B} \subseteq \{u \in \mathcal{U}_{(0,t)} \mid \forall (i, j) \in \mathcal{I}^\Delta, \text{ for a.e. } r \in (0, t), |\xi_r^i - \xi_r^j| \neq 0\}$.

Let $\tilde{\mathcal{A}}_{(0,t)} \doteq C((0, t); \mathcal{M}_{(0,\infty)})$ and $\tilde{\mathcal{A}}_{(0,t)}^B \doteq C((0, t); \mathcal{M}_{\mathbb{R}})$, where $\mathcal{M}_{\mathbb{R}}$ denotes the set of arrays indexed by $(i, j) \in \mathcal{I}^\Delta$ with elements in \mathbb{R} , and where we note that the former is a subset of the latter, which is a Banach space.

Lemma 14: Let $x \in \mathbb{R}^{3n}$, $t \in (0, \infty)$ and $\tilde{\mathcal{B}} \subseteq \mathcal{U}_{(0,t)}$. Then, $W(t, x) = \text{stat}_{u \in \mathcal{B}} \text{stat}_{\tilde{\alpha} \in \tilde{\mathcal{A}}_{(0,t)}} J(t, x, u, \tilde{\alpha})$, where $J(t, x, u, \tilde{\alpha}) \doteq \int_0^t T(u_r) - \tilde{V}(\xi_r, \tilde{\alpha}_r) dr + \phi(\xi_t)$. Further, if $\mathcal{A} \subset \tilde{\mathcal{A}}_{(0,t)}$ is open and such that $\tilde{\alpha}^{i,j} \in \mathcal{A}$ where $\tilde{\alpha}_r^{i,j} = \tilde{\alpha}_{i,j}(\xi_r)$ for all $(i, j) \in \mathcal{I}^\Delta$ and a.e. $r \in (0, t)$, where $\xi_r = x + \int_0^r u_\rho d\rho$, then $W(t, x) = \text{stat}_{u \in \mathcal{B}} \text{stat}_{\tilde{\alpha} \in \mathcal{A}} J(t, x, u, \tilde{\alpha}) = \text{stat}_{u \in \mathcal{B}} J(t, x, u, \tilde{\alpha})$.

If one is able to reorder the staticization operations, the result may be decomposed as

$$W(t, x) \doteq \text{stat}_{\tilde{\alpha} \in \mathcal{A}} \tilde{W}(t, x, \tilde{\alpha}),$$

$$\tilde{W}(t, x, \tilde{\alpha}) \doteq \text{stat}_{u \in \mathcal{B}} \left\{ \int_0^t T(u_r) - \tilde{V}(\xi_r, \tilde{\alpha}_r) dr + \phi(\xi_t) \right\}.$$

Suppose ϕ is a quadratic form, say $\phi(x; z) \doteq \frac{1}{2}(x - z)^T P_0(x - z) + \gamma_0$. Then,

$$\tilde{W}(t, x, \tilde{\alpha}) = \frac{1}{2}(x^T P_t^{\tilde{\alpha}} x + x^T Q_t^{\tilde{\alpha}} z + z^T Q_t^{\tilde{\alpha}} x + z^T R_t^{\tilde{\alpha}} z + \gamma_t^{\tilde{\alpha}}),$$

where $P_t^{\tilde{\alpha}}, Q_t^{\tilde{\alpha}}, R_t^{\tilde{\alpha}}$ may be obtained from solution of $\tilde{\alpha}$ -indexed differential Riccati equations (DREs), and $\gamma_t^{\tilde{\alpha}}$ is obtained from an integral. The means by which this may be utilized for efficient generation of fundamental solutions is indicated in the above-noted references. The key is, of course, the ability to invert the order of the staticization operators. Noting that J is semi-quadratic in u and uniformly Morse in $\tilde{\alpha}$, one obtains the following.

Theorem 15: Let $t \in (0, \infty)$ and $x \in \mathbb{R}^{3n}$. Suppose $W(t, x)$ given by (25) exists. Let $\tilde{\alpha}^{i,j} \in \tilde{\mathcal{A}}_{(0,t)}$ be as in Lemma 14, and $D > |\tilde{B}_3^{\tilde{\alpha}}(\tilde{\alpha})|$. Let $\mathcal{A} \doteq \{\tilde{\alpha} \in \tilde{\mathcal{A}}_{(0,t)} \mid |\tilde{B}_3^{\tilde{\alpha}}(\tilde{\alpha})| < D\}$. Then,

$$\begin{aligned} W(t, x) &= \text{stat}_{u \in \mathcal{B}} \text{stat}_{\tilde{\alpha} \in \mathcal{A}} J(t, x, u, \tilde{\alpha}) = \text{stat}_{(u, \tilde{\alpha}) \in \mathcal{B} \times \mathcal{A}} J(t, x, u, \tilde{\alpha}) \\ &= \text{stat}_{\tilde{\alpha} \in \mathcal{A}} \text{stat}_{u \in \mathcal{B}} J(t, x, u, \tilde{\alpha}). \end{aligned}$$

B. Schrödinger IVPs

We briefly discuss the application to Schrödinger IVPs. In this case, the dynamics are now stochastic and complex-valued. In this case we consider only the problem of a single particle in a central Coulomb field. The IVP is

$$0 = i\hbar \psi_t(s, y) + \frac{\hbar^2}{2m} \Delta \psi(s, y) - \psi(s, y) V(y), \quad (s, y) \in \mathcal{D},$$

$$\psi(0, y) = \psi_0(y), \quad y \in \mathbb{R}^n,$$

where $m \in (0, \infty)$ denotes particle mass, initial condition ψ_0 takes values in \mathbb{C} , V denotes the Coulomb potential function, Δ denotes the Laplacian with respect to the space (second) variable, $\mathcal{D} \doteq (0, t) \times \mathbb{R}^n$, and subscript t will denote the derivative with respect to the time variable (the first argument of ψ here) regardless of the symbol being used for time in the argument list. We consider what is sometimes referred to as the Maslov dequantization of the solution of the Schrödinger equation (cf. [11]), which as noted above, is $S : \mathcal{D} \rightarrow \mathbb{C}$ given by $\psi(s, y) = \exp\{\frac{i}{\hbar} S(s, y)\}$. We also extend the space from \mathbb{R}^n to \mathbb{C}^n , and reverse the time variable. The resulting transformed problem is given by [12], [14], [15]

$$0 = S_t(s, x) + \frac{i\hbar}{2m} \Delta S(s, x) + H(x, S_x(s, x)),$$

$$(s, x) \in \mathcal{D}_{\mathbb{C}} \doteq (0, t) \times \mathbb{C}^n, \quad (26)$$

$$S(t, x) = \phi(x), \quad x \in \mathbb{C}^n. \quad (27)$$

$$H(x, p) \doteq -\left[\frac{1}{2m}|p|_c^2 + V(x)\right]$$

$$= \text{stat}_{u^0 \in \mathbb{C}^n} \left\{ (u^0)^T p + \frac{m}{2} |u^0|_c^2 - V(x) \right\},$$

where for $x \in \mathbb{C}^n$, $|x|_c^2 \doteq \sum_{j=1}^n x_j^2$. We fix $t \in (0, \infty)$, and allow s to vary in $(0, t]$.

Under certain conditions, the solution of this dequantized form of the Schrödinger IVP has a representation in the form of the value function of staticization controlled diffusion equation [15]. In particular, we suppose the solution satisfies $|S_{xx}| \leq C(1 + |x|^{2q})$ for some $q \in \mathbb{N}$. We let (Ω, \mathcal{F}, P) be a probability triple. Let $\{\mathcal{F}_s \mid s \in [0, t]\}$ denote a filtration on (Ω, \mathcal{F}, P) , and let B_\cdot denote an \mathcal{F} -adapted Brownian motion taking values in \mathbb{R}^n . For $s \in [0, t]$, let

$\mathcal{U}_s \doteq \{u : [s, t] \times \Omega \rightarrow \mathbb{C}^n \mid u \text{ is } \mathcal{F}_\cdot\text{-adapted, right-continuous and such that } \mathbb{E} \int_s^t |u_r|^m dr < \infty \forall m \in \mathbb{N}\}$.

We will be interested in diffusion processes given by

$$\xi_r = \xi_r^{(s, x)} = x + \int_s^r u_\rho d\rho + \sqrt{\frac{\hbar}{m} \frac{1+i}{\sqrt{2}}} \int_s^r dB_\rho$$

where $x \in \mathbb{C}^n$, $s \in [0, t]$, $u \in \mathcal{U}_s$. For $s \in (0, t)$ and $\hbar \in (0, 1]$, we define payoff $J(s, \cdot, \cdot) : \mathbb{C}^n \times \mathcal{U}_s \rightarrow \mathbb{C}$ and stationary value, $\bar{S} : \mathcal{D}_{\mathbb{C}} \rightarrow \mathbb{C}$ by

$$J(s, x, u) \doteq \mathbb{E} \left\{ \int_s^t \frac{m}{2} |u_r|_c^2 - V(\xi_r) dr + \phi(\xi_t) \right\},$$

$$S(s, x) \doteq \text{stat}_{u \in \mathcal{U}_s} J(s, x, u) \quad \forall (s, x) \in \mathcal{D}_{\mathbb{C}}.$$

The Coulomb potential generated by a point charge in the central field (extended to complex domain) takes the form of $V(x) \doteq -\frac{\hat{\mu}}{\sqrt{|x|_c^2}} = -(\frac{3}{2})^{3/2} \hat{\mu} \text{stat}_{\bar{\alpha} \in \mathcal{A}^R} \left\{ \alpha - \frac{\bar{\alpha}^3 |x|_c^2}{2} \right\} \doteq -\bar{c} \text{stat}_{\bar{\alpha} \in \mathcal{A}^R} \left\{ \alpha - \frac{\bar{\alpha}^3 |x|_c^2}{2} \right\}$, where $\mathcal{A}^R \doteq \{\bar{\alpha} = r[\cos(\theta) + i \sin(\theta)] \in \mathbb{C} \mid r \geq 0, \theta \in (\frac{-\pi}{2}, \frac{\pi}{2}]\}$, and for $x \in \mathbb{C}^n$, $|x|_c^2 \doteq \sum_{j=1}^n x_j^2$, $\hat{\mu}$ is a constant, and $\bar{c} \doteq (\frac{3}{2})^{3/2} \hat{\mu}$.

Lemma 16: Let $\mathcal{A}_{(s, t)} \doteq L^2(\Omega; L^2([s, t]; \mathcal{A}^R))$. Then

$$\text{stat}_{\bar{\alpha} \in \mathcal{A}_{(s, t)}} \mathbb{E} \left\{ \int_s^t \frac{m}{2} |u_r|_c^2 + \bar{c} [\bar{\alpha}_r - \frac{\bar{\alpha}_r^3 |\xi_{2|_c}^2}{2}] dr + \phi(\xi_t) \right\}$$

$$= \mathbb{E} \left\{ \int_s^t \frac{m}{2} |u_r|_c^2 + \bar{c} \text{stat}_{\bar{\alpha} \in \mathcal{A}^R} [\bar{\alpha} - \frac{\bar{\alpha}^3 |\xi_{2|_c}^2}{2}] dr + \phi(\xi_t) \right\}.$$

The problem of solving for $S(s, x)$ then becomes that of finding the stationary-action value function given by

$$S(s, x) \doteq \text{stat}_{u \in \mathcal{U}_s} \text{stat}_{\bar{\alpha} \in \mathcal{A}_{(s, t)}} \mathbb{E} \left\{ \int_s^t \frac{m}{2} |u_r|_c^2 + \bar{c} [\bar{\alpha}_r - \frac{\bar{\alpha}_r^3 |\xi_{2|_c}^2}{2}] dr + \phi(\xi_t) \right\} \quad \forall (s, x) \in \mathcal{D}_{\mathbb{C}}.$$

Again, the problem becomes that of interchanging the order of the staticization operators. Once that is achieved, the functional inside the staticization over $\bar{\alpha}$ may be solved through DREs.
